

In 2011 and 2012, we conducted several expeditions to eastern Panama for the purpose of studying the herpetofauna of the region. We collected numerous specimens, among which were a considerable number of salamanders of the genus *Bolitoglossa*. We found all of the species expected for the area, except for *B. cuna*. After applying an integrative analysis, which included barcoding, morphology, and biogeography, we uncovered specimens that we were unable to assign to any known species. In the following study we revise the subgenus *Eladinea*, to which all of the eastern Panamanian species have been assigned, provide detailed information on these species, and describe a new species from a private reserve (Reserva Natural Privada Cerro Chucanti) in the Cordillera de Majé. 📷 © Anand Varma

A new species of *Bolitoglossa* (Amphibia: Plethodontidae) from eastern Panama, with comments on other members of the *adspersa* species group from eastern Panama

ABSTRACT: We describe a new species of *Bolitoglossa* from Cerro Chucantí, Cordillera de Majé, Provincia de Darién, Panama. A phylogenetic analysis based on molecular data provides evidence for the assignment of the new taxon to the *Bolitoglossa adspersa* species group. The new species differs in color pattern and morphometrics from all other congeners found in eastern Panama. Additionally, we include comments on the other species of salamanders known to occur in the region.

Key Words: Barcoding, *Bolitoglossa biseriata*, *Bolitoglossa chucantiensis* sp. nov., Darién, *Eladinea*, morphology, phylogeny.

RESUMEN: Describimos una nueva especie de *Bolitoglossa* de Cerro Chucantí, Cordillera de Majé, Provincia de Darién, Panamá. Un análisis filogenético basado en datos moleculares proporciona evidencia de la asignación del nuevo taxón al grupo de especies *Bolitoglossa adspersa*. La nueva especie se diferencia en el patrón de color y morfometría de todos los otros congéneres que se encuentran en el este de Panamá. Además, incluimos comentarios sobre las otras especies de salamandras que son conocidas en la región.

Palabras Claves: *Bolitoglossa biseriata*, *Bolitoglossa chucantiensis* sp. nov., códigos de barras, Darién, *Eladinea*, morfología, filogenia.

INTRODUCTION

The Neotropical salamanders (Plethodontidae) are dominated by the genus *Bolitoglossa*, globally the most diverse salamander genus (128 species) with a distribution extending from northeastern Mexico and across Central America, and into South America (AmphibiaWeb, 2014). With a surface area of only 75,416 km² Panama is home to 29 species of plethodontids (AmphibiaWeb, 2014); the highest diversity is in the western part of the country, where 17 species of *Bolitoglossa* are found, but only four of these species are known to occur in eastern Panama (Jaramillo et al., 2010). Two subgenera have been recognized for lower Central America and South America, *Bolitoglossa* (*sensu stricto*) and *Eladinea* (*sensu* Parra-Olea et al., 2004). *Eladinea* is comprised of the *adpersa*, *epimela*, *schizodactyla*, and *subpalmata* species groups. Of these, the distribution of only the *adpersa* species group extends far to the south, reaching central Bolivia (Frost, 2014).

The *adpersa* species group consists of 33 known species, of which four are known from eastern Panama (*B. biseriata*, *B. cuna*, *B. medemi*, and *B. taylori*); two of these are endemic to the Pirre (*B. taylori*) and San Blas (*B. cuna*) mountain ranges (Raffaëlli, 2007; Köhler, 2011; Acosta-Galvis and Gutiérrez-Lamus, 2012; Acevedo et al., 2013). Neotropical salamanders usually are difficult to identify due to their similarities in color pattern variation and morphology (Wake, 1970; Wake and Lynch, 1976; García-París et al., 2000; Wake et al., 2007; Fermin et al., 2012). The few species from eastern Panama, however, are easy to distinguish from each other; the only exceptions are *B. biseriata* Tanner, 1962 and *B. cuna* Wake et al., 1973, which are similar in overall appearance and only can be differentiated by their head width and the number of maxillary teeth (Wake et al., 1973). Wake et al. (1970) noted the occurrence of *B. phalarosoma* Wake and Brame, 1962 in the Jaqué-Imamadó divide of eastern Panama, but this record remains unsubstantiated because the authors did not indicate voucher specimens or provide other supportive data; other authors (e.g., Raffaëlli, 2007; Acosta-Galvis and Gutiérrez-Lamus, 2013) have stated that the identity of the salamanders referred to as *B. phalarosoma* and an undescribed species noted by Wake et al. (1970) needs to be confirmed. At this point, therefore, we do not consider *B. phalarosoma* as a member of the Panamanian herpetofauna. The remaining two species known to occur in eastern Panama are *B. taylori* Wake, et al., 1970 and *B. medemi* Brame and Wake, 1972.

During recent expeditions to the Darién, Jingurudó, Majé, Pirre, and San Blas mountain ranges, we collected specimens of three salamander species known to occur in eastern Panama (*B. biseriata*, *B. medemi*, and *B. taylori*), as well as a single adult specimen of an undescribed species of salamander from the Cordillera de Majé and a related salamander (an apparent juvenile) from the Cordillera de Jingurudó. We identified both of these specimens as members of the genus *Bolitoglossa* based on the following characteristics: absence of a sublingual fold, presence of well-developed hands and feet, presence of extensive digital webbing, and a count of 13 costal grooves between the limbs (Parra-Olea et al., 2004). Herein we describe the specimen from the Cordillera de Majé as a new species, and discuss its relationship to the juvenile specimen from the Cordillera de Jingurudó. We also provide data on molecular and morphological variation for the four species of *Bolitoglossa* found in the region.

MATERIALS AND METHODS

We conducted our fieldwork in the Darién, Jingurudó, Majé, Pirre, San Blas, and Sapo mountains of eastern Panama, (Fig. 1); see Appendix 2 for details on the collecting areas. We recorded georeferences by using a Garmin GPSmap 60CSx, in the WGS 1984 datum format and given in decimal degrees, and created the maps in ArcGIS 10 (ESRI, 2010). We euthanized the specimens collected with the euthanasia solution T61, fixed them with a preservative solution of 5ml formalin (36%) in 1L ethanol (94%), and subsequently stored them in ethanol (70%).

Morphology

We followed the methodology of Boza-Ovideo et al. (2012) for measuring the morphological characters of the holotype, and used a dial precision caliper under a dissecting microscope (Leica MZ 12) rounded to the nearest 0.1 mm. We examined the following characters: snout–vent length (standard length) from the tip of snout to the posterior end of vent (SVL), tail length from the posterior end of vent to the tip of the tail (TL), distance from the gular fold to the tip of the snout (SG), head width at the greatest width of the head (HW), head depth (height) at the posterior angle of the jaw (HD), eyelid length (EL), eyelid width (EW), distance from the anterior margin of the orbit to the tip of the

snout (ES), horizontal eye diameter (ED), intercanthal distance (IC), interorbital distance between the eyelids (IO), tip of the snout to the point where the forelimb articulates with the body (SF), internarial distance (IN), snout projection (SP), shoulder width (SW), snout to the anterior angle of the vent (SAV), axilla-groin distance (AX), hind limb length from the groin to the tip of longest digit (HLL), forelimb length from the axilla to the tip of the longest digit (FLL), hand width at the widest extent (HAW), foot width at the widest extent (FW), length of the 3rd toe (T3), and length of the 5th toe (T5); we counted premaxillary teeth (PMT), maxillary teeth (MT), and vomerine teeth (VT) by using a dissecting microscope; we provide MT and VT for left and right sides, respectively. We followed Brcko et al. (2013) for the following characters: costal folds between the adpressed limbs of the straightened specimen (limb interval, LI, as a measure of relative limb length), mental gland width (WMG), and mental gland length (LMG). We ran an exploratory analysis among the different morphological characters, since not enough useful morphological information was available (see Table 1) to conduct a statistical test among all the species; we present these diagnostics characters in graphs, showing only the range between the maximum and minimum values. We follow Köhler (2012) for the description of coloration in life and in ethanol. We used the keys to the genus *Bolitoglossa* in Savage (2002) and Köhler (2011) for a preliminary identification of the specimens collected. We obtained data for morphological characters and tooth counts for comparisons within the *adpersa* species group from the following original species descriptions and species revisions: Tanner (1962), Wake and Brame (1962), Brame and Wake (1972), Wake et al. (1973), Wake and Lynch (1976), Acosta-Galvis and Gutiérrez-Lamus (2012), and Acevedo et al. (2013). We derived osteological information on the holotype from radiographs. The capitalized colors and color codes (the latter in parentheses) are those of Köhler (2012). We followed Köhler (2012) for the terminology of markings used in the color descriptions.

Molecular Analysis

We extracted DNA from fresh liver tissue using the protocol of Ivanova et al. (2006). We amplified the mitochondrial 16S mtDNA using a Mastercycler pro S (Eppendorf, Hamburg, Germany), and performed the initial denaturation for 2 min at 94°C, which was followed by 40 cycles with denaturation for 35 s at 94°C, hybridization for 35 s at 48.5°C, and elongation for 60 s at 72°C; the final elongation proceeded for 7 min at 94°C. The reaction mix contained 1 µL DNA template, 2.5 µL Reaction Buffer ×10 (PeqGold), 4 µL 2.5 mM dNTPs, 0.4 µL (containing 2.5 units) Taq Polymerase (PeqLab), 14.1 µL H₂O, 1 µL 25 mM MgCl₂, and for 16S 1 µL per primer (containing 10 pmol, forward: L2510, 5'-CGCCTGTTTATCAAAAACAT-3'; reverse: H3056, 5'-CCGGTCTGAACTCAGATCACGT-3'; eurofins MWG Operon); the COI gene was sequenced by the Southern China DNA Barcoding Center; because this project was developed along with a larger barcoding project for the amphibians and reptiles of eastern Panama, we only used the standardized genetic markers 16S and COI (Paz and Crawford, 2012), as financial resources were limited to these markers. We compared the molecular data of our specimens with the available sequences for the species of *Bolitoglossa* present in Central America and South America, which we obtained from recent publications (Boza-Oviedo et al., 2012; Hertz et al., 2013; Elmer et al., 2013; Acevedo et al., 2013). We aligned the obtained sequences with ClustalX (Thompson et al., 1997). We present a list of the specimens included in our genetic analysis, with the corresponding GenBank accession numbers, in Appendix 1. The final alignment of the 16S mtDNA comprised 32 sequences of 439 bp in length, of which 111 sites are variable and 74 are parsimony-informative (excluding outgroups). We computed Kimura 2-parameter (K2P) pairwise genetic distances for 16S and COI separately, using MEGA5 (Tamura et al. 2011). For phylogenetic inference we used 16S mtDNA (we did not include COI, because it was not available for most species of *Bolitoglossa*), and ran a Maximum Likelihood (ML) analysis with 1,000 bootstrap replicates using MEGA5, using the Kimura 2 parameter model. We used JModeltest 0.1.1 (Posada 2008) under the corrected Akaike Information Criterion (AICc) to select the substitution model for the Bayesian analysis. We determined TIM3+G as the best-fitting substitution model, and ran a Bayesian phylogenetic analysis in MrBayes 3.1.2 (Huelsenbeck and Ronquist, 2001) for 10,000,000 generations with four default chains, sampling every 100 generations and subsequently discarding 5% as burn-in. For the tree including all the species of *Bolitoglossa*, we used *Oedipina complex*, *Nototriton picadoi*, and *N. matama* as outgroups. For the tree including only the *adpersa* species group, we used *B. colonea* and *B. schizodactyla* as outgroups.

Fig. 1. Distribution of species of *Bolitoglossa* in eastern Panama. *Bolitoglossa* sp. (Black Square) pertains to specimen MHCH 2663 from the Cordillera de Jingurudó; shaded areas with borders represent the principal mountain ranges in eastern Panama, with elevations above 500 m a.s.l. (names of mountain ranges inside the shaded areas).

Table 1. Measurements and morphological proportions for the *Bolitoglossa* spp. from eastern Panama. We included data for *B. medemi*, *B. taylori*, and *B. cuna* taken from the species descriptions.

RESULTS

The salamander found on Cerro Chucantí in the Cordillera de Majé differs in color pattern and tooth counts from all its known congeners occurring in eastern Panama (Table 1) and South America. The new species showed a genetic distance to all species in the group of 7.5% (5.5–10.4%; *n* = 16) for 16S and 19.2% (5.6–28.8%; *n* = 4) for COI (only species from eastern Panama were included). In a Bayesian phylogenetic analysis based on all the taxa of *Eladinea* and *Bolitoglossa* available on GenBank (see Appendix 2), the new species clustered together with samples from the *adpersa* species group. In the Cordillera de Jinguirudó, a distance of ca. 140 km from the locality of our new species, we found a very small salamander (SVL 17.9 mm) that we were unable to assign to any described species. Based on its disproportionately large head, the specimen apparently is a juvenile, and thus we excluded it from morphological comparisons with other species. According to the mtDNA results, the specimen is closely related to our new species, as it shows a K2P genetic distance of 1.4% for 16S and 5.6% for COI. Our mtDNA analysis shows that the most variable species was *B. biseriata*, with an average within-group genetic distance of 2.4% (*n* = 5) for 16S

(only one sample for COI). A specimen of *B. biseriata* from Río Púculo (SMF 97139) was 3.5% divergent from one collected on the Cordillera de San Blas (SMF 97127) and another from the Río Tuquesa (MHCH 2659), but showed only 1.2% divergence from a second specimen from the Río Tuquesa (MHCH 2658). *Bolitoglossa biseriata* appears to be a polymorphic species or a complex with several cryptic species, possibly paralleling the high variation in dorsal color pattern (Fig. 8), in hand and foot shapes (Fig. 7 G–L), and genetic distances (Tables 2–3). Genetically, the other two species were less variable: *B. taylori* (0.2 % K2P) and *B. medemi* (1.7 % K2P).

Table 2. Mean genetic distances of 16S mtDNA among the *Bolitoglossa* samples used in the phylogenetic analysis (Fig. 2); numbers below diagonal are for K2P distances, and numbers above are standard error estimates (in percentage).

Fig. 2. Maximum likelihood consensus tree of 16S mtDNA, for the *Bolitoglossa adspersa* species group; specimen labels refer to the collection or museum number; scale bars refer to the number of substitutions per site. Maximum likelihood bootstrap values are shown below the branch, Bayesian posterior probabilities ≥ 0.95 are shown with an asterisk above the branch, \leq probabilities are not shown. We used *B. colonnea* and *B. schizodactyla* as outgroups.

Our new species is most similar to *Bolitoglossa taylora* in body proportions, but the two species can be distinguished from one another by their color pattern and shape of their hands and feet (Fig. 7). We provide a formal description of the new species below.

***Bolitoglossa chucantiensis* sp. nov.**

Common names: Chucantí Salamander (English); Salamandra de Chucantí (Spanish). Fig. 3, Fig. 4, Fig. 7 A–B.

Holotype: SMF 97141 (original field number AB 1063), an adult male from Panama, Provincia de Darién, Cordillera de Majé, Distrito de Chepigana, Río Congo Arriba, Reserva Natural Privada Cerro Chucantí, (8.8034°N, 78.4601°W; 1,424 m elev.), collected 3 December 2013 by Abel Batista and Konrad Mebert.

Diagnosis: A salamander of the genus *Bolitoglossa* and the subgenus *Eladinea* (as evidenced by the presence of a first caudal vertebra that bears unbranched transverse processes, and a prominent mental gland in males; Parra-Olea et al., 2004; Fig. 4). Our mtDNA sequence data show that this species is nested within the *adspersa* group. *Bolitoglossa chucantiensis* can be distinguished from all other eastern Panamanian and South American species of *Eladinea* by the presence of a higher number of maxillary teeth in proportion to the SVL, by the presence of completely webbed feet and hands, by its unique color pattern, and by a mtDNA genetic distance > 5.5%. *Bolitoglossa chucantiensis* is a small salamander (SVL 47 mm) with a slight indentation evident between the toe and fingertips, and in which only the longest toe and finger are pointed; the tail is relatively long (TL/SVL = 1.2); the dorsal coloration is brown, with patches of yellow speckling; and a prominent rounded hedonic mental gland and a postiliac glands are present in males. *Bolitoglossa chucantiensis* can be distinguished from other species in the *adspersa* group by the following characteristics (with contrasting features for *B. chucantiensis* in parentheses or brackets; see Table 1 for additional details): it differs from all the South American species (Acevedo et al., 2013; Brcko et al., 2013; García-Gutiérrez et al., 2013) by the presence of a higher number of maxillary teeth in males; and it differs from its closest relatives in South America by more than 5.5% of K2P pairwise genetic distance (*B. adspersa*, *B. altamazonica*, *B. leandrae*, *B. nicefori*, *B. orestes*, *B. palmata*, *B. paraensis*, *B. peruviana*, *B. sima*, *B. tamaense*, and *B. mucuyensis*). *Bolitoglossa chucantiensis* can be distinguished from the closely related *B. guaneae* by several characters. In *B. guaneae* the SVL is shorter (31.53–41.56 mm [vs. 47.3]), the 3rd finger and toe tips are pointed and protruding (vs. a slight indentation is evident between the toe and fingertips), its coloration is pale brown to gray in preservative, and in life the coloration is dark brown, sometimes mottled or streaked with white (vs. the dorsal ground color is dark brown and contains patches of yellow speckling); similarly, *B. chucantiensis* can be differentiated from *B. biseriata* because the head of this species is shorter (an HL/SVL ratio of 8.7–10.5 [vs. 11.74]), the hand and foot are narrower (vs. a broad hand and foot), the dorsal ground color is brown, cream, or red and sometimes is patterned with single small dark or yellow dots (vs. the dorsal ground color is dark brown, and contains patches of yellow speckling that are paler toward the head; Fig. 3); although males are not available for comparison, 33–38 vomerine teeth are present in female *B. cuna* (vs. 25), the head and hands of this species are narrower in relation to the body length, and fewer maxillary teeth are present (Fig. 6). Additionally, *B. cuna* is a lowland species (vs. a highland species) found near sea level (see Discussion), and the body is more slender than that of *B. chucantiensis*. *Bolitoglossa medemi* is a species with 28–59 maxillary teeth (vs. 75), generally contains fewer teeth in relation to the body length (0.8–1.3 vs. 1.6), and the head is broader. *Bolitoglossa taylori* is a species with extensive webbing (vs. completely webbed), and its dorsal coloration usually consists of small or large blotches (vs. patches of yellow speckling).

Description of holotype: Male, SVL 47.3 mm; 75 MT, 2 PMT, the PMT do not pierce the lip, 23 VT; trunk length 23.18 mm between the levels of the axilla and groin; the head is moderately broad with an SVL/HW ratio of 6.2; the head is distinctly wider than the neck; the distance across shoulders is 6.0 mm; the horizontal orbit diameter is 75% of the snout length; the eyes protrude beyond the lateral margins of the head and are visible in dorsal view; the nasolabial protuberances are evident and developed; the snout is truncate in dorsal view and slightly rounded to truncate in lateral view; the canthus rostralis is indistinct; the nostrils are small and located near the tip of the snout; a mental gland is present, oval, WMG 3.1 mm, LMG 2.6 mm; the body is cylindrical, with 13 costal grooves; the hands and feet are moderately broad (HAW = 7%, HFW = 10% of SVL), the feet are completely webbed, subterminal pads are evident on digits 2–3–4 on the foot and 2–3 on the hand; the fingers, in order of decreasing length, are III–II–IV–I; the toes are III–IV–II–V–I (Figs. 3F, 7 A–B); the tail is long, 55.0 mm and exceeding the standard length 1.17 of SVL; the hind limb is 10.0 mm, the forelimb is 11.0 mm; the maxillary teeth are relatively numerous, MT/SVL 1.6 times, and extend to about the level of the end of the eye; the vomerine teeth border the anterior orbit shape in the roof of mouth; paravomerine teeth are present and numerous; the tongue is enlarged and rounded in its anterior tip, with a concavity in the center; the prevomer clearly projects from the level of the palate, bearing

vomerine teeth in long, slightly arched series, and extends laterally almost to the center of the roof of the mouth. We include other measurements and counts in Table 1.

Coloration of the holotype in life (Fig. 3): The color pattern of the holotype was recorded the day after capture (at 1730 h), as follows: the upper dorsum is Crimson (62); the flanks, tail, and limbs are Maroon (39), strongly speckled with Straw Yellow (53); the iris is Light Yellow Ocher (13) with Hazel (26) reticulations, and the eyelids are Straw Yellow (53); the venter is translucent with Warm Sepia (40) pigment, with the throat Straw Yellow (53); the ventral surfaces of the limbs are speckled with Straw Yellow (53).

Coloration of the holotype in alcohol: The color pattern of the holotype was recorded after the specimen spent about two years in ethanol (70%), as follows: the upper dorsum is Verona Brown (37); the head region is Vandyke Brown (282); the flanks and limbs are Grayish Olive (274), speckled with Glaucous (272); the tail is Dusky Brown (285); the eyelids are Brownish Olive (292); and the venter is Smoke Gray (267).

Osteology (Fig. 4): The vertebral column consists of one atlas, 14 trunk vertebrae, one sacral, two caudosacral vertebrae, and 39 caudal vertebrae, with the first caudal process directed frontally; ribs are present on all the trunk vertebrae except for the last one, and are directed forwardly; the skull is well formed, and the visible structures of the head are the following: premaxilla, maxilla, nasals, vomer bodies, orbitosphenoids, and parasphenoid; the otic capsules are well developed and attached to the squamosals, the quadrates are barely visible and connected to the squamosals; the limbs are well developed; the digits are visible on all the limbs; the phalangeal formula for the hand is 1–2–3–2, and for the foot 1–2–3–3–2; and the metacarpal IV and metatarsal V are broader than the others (Fig. 4).

Habitat and natural history notes: *Bolitoglossa chucantiensis* is known only from the type locality in the eastern Panamanian montane forest (*sensu* Fund and Hogan, 2012; Fig. 1) comprised of trees attaining heights of about 15 m, with their branches densely covered with bromeliads and other epiphytes (e.g., orchids, Loranthaceae), and with palms, vines, and bromeliads dominating the understory. The holotype was found at 2200 h, active on a palm leaf about 1 m above the ground, along a trail 200 m southwest from the ridge top. A drizzling rain had fallen between 1830 and 2100 h, but the conditions had turned calm, with only a slight breeze. Other species of amphibians and reptiles observed in the area that day were: *Oedipina* aff. *complex*, *Diasporus* sp., *Colostethus* aff. *pratti*, *Pristimantis moro*, *P. caryophyllaceus*, *P. cruentus*, *Espadarana prosoblepon*, *Silverstoneia* sp., *Ptychoglossus festae*, *Dendrophidion percarinatum*, and *Geophis* sp.

Etymology: The species name is derived from the name of the mountain (Cerro Chucantí) where the holotype was found, with the Latin suffix *-ensis* indicating a place or locality. Chucantí is the highest point in the Cordillera de Majé, with an elevation of 1,439 m, and is part of the Chucantí Private Cloudforest Reserve, a protected area owned by Guido Berguido.

DISCUSSION

Bolitoglossa chucantiensis is a member of the *adpersa* group of the subgenus *Eladinea*, the only group of the subgenus distributed in eastern Panama and northern South America. The new species can be distinguished from other members of the group by external features (TL/SVL and MT/SVL ratios, a brown dorsal coloration containing patches of yellow speckling) and by its relatively large genetic distance from other species in the group (> 5.5% in 16S and > 16% in COI). Herein we combined morphology and molecular genetics to compare the species of *Bolitoglossa* occurring in eastern Panama. Within the *adpersa* group, several examples of distinct species exhibit a smaller sequence divergence. For example, we analyzed sequences of *B. nicefori*, *B. tamaense*, and *B. leandrae* from Colombia and found a genetic divergence of 2.6% of p and K2P for 16S between the first two species, and only 2.0% of p and K2P for 16S between *B. nicefori* and *B. leandrae*. The mean genetic divergence among these species is 3.0% of K2P (Acevedo et al., 2013). While *B. tamaense* can be distinguished from *B. nicefori* by the different amount of webbing, *B. leandrae* is morphologically similar to *B. tamaense* but shows high maxillary tooth counts (29–30 vs. 35–40) and a distinct elevational distribution (Acosta-Galvis and Gutiérrez-Lamus, 2012; Acevedo et al., 2013). Nevertheless, an even lower genetic divergence (0.5% K2P) has been found for some morphologically well-defined sister species of the genus *Bolitoglossa* (Parra-Olea et al., 2004). Finally, the minimum threshold of 3% of pairwise genetic divergence applied in barcoding analyses of 16S mtDNA of amphibians (Vieites et al., 2009;

Crawford et al., 2010; Jansen et al., 2011) is not consistent to delineate among *Bolitoglossa* spp., as the morphological differences noted above justify the use of an even lower %-divergence to recognize separate species.

Although *B. chucantiensis* can be well differentiated from other species of *Bolitoglossa*, we refrain from assigning our second specimen from the Cordillera de Jingurudó to any recognized taxon. Initially, we treated it as conspecific with *B. chucantiensis* due to their low pairwise genetic distance (1.4% K2P). The recently described species, *B. guaneae* Acosta-Galvis and Gutiérrez-Lamus, 2012, from the Cordillera Oriental of the Colombian Andes, however, appears to exhibit a similar phenotype to our Jingurudó specimen. Unfortunately, neither molecular data nor tissue samples of *B. guaneae* were available for a genetic comparison. Thus, a taxonomic assignment of our Jingurudó specimen must await a proper analysis that includes more Colombian material and/or more specimens from the Cordillera de Jingurudó.

Among the other taxa of *Bolitoglossa* we collected in eastern Panama, we detected exceptionally high variation in morphological and molecular characters in specimens of *B. biseriata*, even within geographically close metapopulations or from the same locality. As already mentioned, the sample from Río Púculo (SMF 97139) is unusual by showing a genetic distance of 3.5% K2P to samples from Río Tuquesa and San Blas (SMF 97127, MHCH 2659), which exceed the suggested threshold of genetic distance for species level within the genus (> 3.0%). The Río Púculo specimen also possesses fully webbed feet (Fig. 7 K–L), which is strikingly different from other specimens of *B. biseriata* sampled in the area. In the context of a sample size too low to reveal the full morphological variation of foot webbing, we provisionally consider this an anomaly. The sample was collected relatively close to the type locality of *B. biseriata* (19.7 km NE) and its genetic distance from other conspecifics (MHCH 2658, S13236) with typical *biseriata* webbing on the feet (Fig. 7 I–J) is much lower (1.7 % of K2P). These facts, together with other morphological similarities, allocate the Río Púculo specimen to *B. biseriata*. Another case of high variation is evident among three *B. biseriata* collected within the Cordillera de San Blas: almost twice as many maxillary teeth are present in SMF 97641 and SMF 97129 than in SMF 97127, found at the same locality (57–61 vs. 36), whereas the typical counts for other specimens collected in Panama range from 18 to 46. Furthermore, molecular distances also are quite variable, as the specimen with high tooth counts, SMF 97641, exhibits 3.1% K2P distance to the syntopic SMF 97127, which has a low tooth count, but only 1.0% K2P distance to MHCH 2658 (an adult male from Río Tuquesa) whose maxillary tooth count is even lower (18 maxillary teeth) and was found at a distance of about 82 km to the northwest. Although SMF 97641 was not included in the phylogenetic analysis due to an incomplete sequence of 16S mtDNA (only 192 bp, no sequence was obtained for COI), its morphological appearance corresponds well to that of other *B. biseriata* from the region (Fig. 8). Due to these incongruences in geographic pattern of molecular and morphological data, we treat *B. biseriata* as a species complex harboring deep conspecific lineages (Vieites et al., 2009; Padial et al., 2010). Therefore, we suggest treating it as a species complex until a larger sample size allows for a more detailed comparative analysis to better understand the extent of morphological and genetic variation. In the view of these data, the validity of *B. cuna* needs to be evaluated. Although Wake et al. (1973) state that the head of *B. cuna* is narrower than that of *B. biseriata*, we did not find any differences in HW/SVL ratio between these species (Fig. 6). The only character that might be useful to differentiate between them is maxillary tooth count (see key below). Since *B. cuna* is known only for the vicinity of the type locality (Solis et al. 2004), molecular data from this locality still are needed to clarify its status in relation to the *B. biseriata* complex, whose members are similar in overall appearance.

Bolitoglossa taylori was the least genetically variable species (average genetic distance within species = 0.2% K2P), but it showed considerable variation in coloration and skin texture (Fig. 10). This variation was documented by Wake et al. (1970: 9), who stated that the dorsal surfaces of *B. taylori* can be “light grayish brown, light brown, yellowish brown, orange-brown, or rich red-brown sometimes with extensive dark brown or black dorsal markings, and often with a dark brown lateral stripe”. Such variability also has been described for other members of the genus (e.g., Vial, 1966; García-París et al., 2000, 2008). We summarize the morphological variation for the species reported from eastern Panama in the key below, and emphasize the importance of conserving Panama’s primary rainforests to enable the survival and long-term persistence of these beautiful and valued amphibians.

Fig. 10. Color variation in *B. taylori*. A = SMF 97136; B = SMF 97135; C = SMF 97133; D = SMF 97138; E = MHCH 2666; F = MHCH 2669; G = left foot (SMF 97137); and H = left hand (SMF 97137).

Key to the genus *Bolitoglossa* in eastern Panama

- 1a. Tail length equal to SVL or distinctly longer, (TL/SVL = 1.04–1.28); tail cylindrical; dorsum mainly red or dark brown, uniform or with cream to yellow blotches or patches with speckles. 2
- 1b. Tail shorter than SVL (TL/SVL = 0.75–1.03); tail cylindrical or laterally compressed; dorsal coloration uniform, bicolored, black, red, or brown. 3
- 2a. Dorsum brown with large patches with yellowish speckling; feet completely webbed, with a slight indentation between tips of toes and fingers. *Bolitoglossa chucantiensis*
- 2b. Dorsum brown, black, cream, or red, without patches of yellow speckling; extensive webbing on feet, evident indentation between tips of toes and fingers. *Bolitoglossa taylori*
- 3a. Tail laterally compressed, tip of 3rd toe and 3rd finger sharply pointed, abruptly protruding the hand and foot. *Bolitoglossa medemi*
- 3b. Tail cylindrical; tip of 3rd toe and 3rd finger not abruptly protruding the hand or foot. 4
- 4a. More than 66 maxillary teeth. *Bolitoglossa cuna*
- 4b. Fewer than 61 maxillary teeth. *Bolitoglossa biseriata*

Acknowledgments.—Scientific permits: 2011 (SC/A-37-11), 2012 (SC/A-33-12), and exportation permits 2012 (SC/A-33-12), 2013 (SEX/A-7-13) were provided by ANAM, Panama, and T. Quintana (Cacique General del área de Sambú) from the “despacho del cacique Regional” Comarca Emberá-Wounaan, Panama. A special thanks go to the indigenous people of Embera from Puerto Indio and Pavarandó, especially to D. Berrugate (Secretary of the Emberá-Wounaan congress, Sambú); and L. Caibera (Noko of Pavarando village) and his family who allowed us to enter their autonomous territory and kindly supported our work logistically. We are very grateful to Don Faustino, Hermelinda, and family, who provided us shelter in their nice sustainable farm at la Moneda’s village during our travels to Darién. We thank Yorlis Cáceres, Daniel Cáceres, Isaac Pizarro, Gustavo Dogirama, Mario Cuñapa, Anselmo Caicedo, Hugo Martínez, Marcial Sabúgara, Amadiel Chaquí, Elacio Méndez and Gilberto Torres for field assistance. To Guido Berguido for his support during our staying at the Chucanti private reserve. We also thank Adrián García and Sean Rovito for their valuable comments during the review process, which improved the manuscript, and Loraine Perez for her patience with Abel Batista during his stay in the field and abroad during the development of this project. This work was supported financially by the Secretaría de Ciencia y Tecnología (SENACYT), Instituto para la Formación y Aprovechamiento de los Recursos Humanos (IFARHU), Panama; the molecular work was supported partially by MWH, Panama.

Abel Batista is a Panamanian who received a Masters degree in Biological Sciences at the Universidad de los Andes in Bogotá, Colombia, and currently is a Ph.D. student at Senckenberg Research Institute, Frankfurt am Main, Germany. Abel is specializing in the study of amphibians and reptiles from eastern Panama, and his research focuses on barcoding, biogeography, conservation, taxonomy, and bioacoustics.

Gunther Köhler received a degree in Veterinary Medicine (Staatsexamen) at the University Gießen, Germany in 1993 and a doctoral degree at Goethe University Frankfurt am Main, Germany in 1995; since that time he has been the Curator of Herpetology at the Senckenberg Research Institute, Frankfurt am Main, Germany. His research focuses on the Neotropical herpetofauna, primarily that of Central America and Mexico. To date, Gunther has authored 26 books and 165 research papers on amphibians and reptiles.

Konrad Mebert is an independent researcher and international project coordinator based in Switzerland, who focuses on reptiles. After completing a Master's degree on geographic variation and the effects of inbreeding on the Dice Snake at the University of Zürich, Switzerland, and a doctoral degree on hybrid zones in North American water snakes at Old Dominion University, Virginia, he currently is associated with the University of Basel in Switzerland. To date, Konrad has authored more than 80 professional and popular publications and two books on such topics as evolution, ecology, biodiversity, and conservation. His passion for photography and love of travel have led him to all continents except Australia, but his preference is the Neotropics where he has developed a special affection for Panama.

Milan Vesely is a biologist (Ph.D.) who is vice-president of Czech Herpetological Society. An assistant professor in the Department of Zoology at Palacky University in Olomouc, Czech Republic, for almost two decades Milan has focused his research interests on the herpetofauna of Central America. During his career, Milan has authored numerous popular and scientific papers on amphibian and reptile taxonomy, ecology, and parasites, and also is co-author (with Gunther Köhler and Eli Greenbaum) of a book entitled *The Amphibians and Reptiles of El Salvador*.
